The formal definition of spread spectrum is more precise: an RF communications system in which the baseband signal bandwidth is intentionally spread over a larger bandwidth by injecting a higher frequency signal (Figure 1). As a direct consequence, energy used in transmitting the signal is spread over a wider bandwidth, and appears as noise.

Introduction Spread Spectrum refers to a system originally developed for military applications, to provide secure communications by spreading the signal over a large frequency band. Figure 1 represents a narrow band signal in the frequency domain. These narrowband signals are easily jammed by any other signal in the same band.

Spread spectrum (SS) technology is used in multiple access communication to increase resistance to signal interference from multiple transmission paths and to increase bandwidth efficiency. In this chapter, we describe several digital modulation techniques that are used in spread spectrum communication. In the analysis of digital modulation, we treat the signals as stationary stochastic processes.
