In JavaScript, the Module pattern is used to further emulate the concept of classes in such a way that we're able to include both public/private methods and variables inside a single object, thus shielding particular parts from the global

scope. What this results in is a reduction in the likelihood of our function names conflicting with other functions defined in additional scripts on the page.

Module Design Pattern in JavaScript JavaScript modules are the most prevalently used design patterns for keeping particular pieces of code independent of other components. This provides loose coupling to support well-structured code. For those that are familiar with object-oriented languages, modules are JavaScript "classes".

The constructor Pattern In classical object-oriented programming languages, a constructor is a special method used to initialize a newly created object once the memory has been allocated for it. In JavaScript almost everything is an object, we have most often interested in object constructors.

Regular expressions are patterns used to match character combinations in strings. In JavaScript, regular expressions are also objects. These patterns are used with the exec () and test () methods of RegExp, and with the match (), matchAll (), replace (), replaceAll (), search (), and split () methods of String.

Earlier, we went through how to define data types in JavaScript through functions and adding methods to the object's prototype. The Prototype pattern allows objects to inherit from other objects, via their prototypes. The prototype pattern is a pattern where objects are created based on a template of an existing object through cloning.

The Loader Pattern constructs a URL with date and time stamp at the end so that the file will not be cached. It sets up jQuery as a dependency on the loader file, then executes a function in the loader. This ensures your custom JavaScript will load after jQuery finishes loading.

Unlike other programming languages, JavaScript doesn't
have access modifiers, that is, you can't declare a variable
as private or public. So the Module pattern is also used to
emulate the concept of encapsulation. This pattern uses IIFE
(immediately-invoked function expression), closures and
function scope to simulate this concept.
